Quality Improvement (QI) offers a proven methodology for improving care for long-term care (LTC) residents in Ontario. In this guide, developed to support the LTC sector, QI refers to a QI team, working towards a defined aim, gathering and reviewing frequent measures and implementing change strategies using rapid cycle improvements. QI science provides tools and processes to assess and accelerate efforts for testing, implementing and spreading QI practices. This guide is an introductory resource to support practitioners of LTC QI in Ontario.

This guide was prepared by Health Quality Ontario (HQO).

We gratefully acknowledge

**INTRODUCTION**

Quality Improvement (QI) is a proven, effective way to improve care for residents and to improve practice for staff. In long-term care (LTC), as in the healthcare system, there are always opportunities to optimize, streamline, develop and test processes, and QI should be a continuous process and an integral part of everyone’s work, regardless of role or position within the organization.

Health Quality Ontario (HQO) has developed this guide to give resident care teams and organizations within the LTC sector in Ontario easy access to well-established QI tools. We provide examples of how to adapt and apply these tools to our Ontario LTC environments.

Our objective is for the guide to help you start and support LTC QI initiatives.

1.1 WHAT IS QUALITY IN HEALTHCARE?

Ontarians share a common vision of a high-performing health system. We want a publicly funded system that is accessible, effective, safe, patient-centred, equitable, efficient, appropriately resourced, integrated and focused on population health. These are the nine attributes of a high-quality health system identified by HQO.

<table>
<thead>
<tr>
<th>ATTRIBUTES OF QUALITY</th>
<th>OUTCOMES</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accessible</td>
<td>People should be able to get the right care at the right time in the right setting by the right healthcare provider.</td>
</tr>
<tr>
<td>Effective</td>
<td>People should receive care that works and is based on the best available scientific information.</td>
</tr>
<tr>
<td>Safe</td>
<td>People should not be harmed by an accident or mistakes when they receive care.</td>
</tr>
<tr>
<td>Patient-centred</td>
<td>Healthcare providers should offer services in a way that is sensitive to an individual's needs and preferences.</td>
</tr>
<tr>
<td>Equitable</td>
<td>People should get the same quality of care regardless of who they are and where they live.</td>
</tr>
<tr>
<td>Efficient</td>
<td>The health system should continually look for ways to reduce waste, including waste of supplies, equipment, time, ideas and information.</td>
</tr>
<tr>
<td>Appropriately Resourced</td>
<td>The health system should have enough qualified providers, funding, information, equipment, supplies and facilities to look after people's health needs.</td>
</tr>
<tr>
<td>Integrated</td>
<td>All parts of the health system should be organized, connected and work with one another to provide high-quality care.</td>
</tr>
<tr>
<td>Focused on Population Health</td>
<td>The health system should work to prevent sickness and improve the health of the people of Ontario.</td>
</tr>
</tbody>
</table>

1.2 WHAT IS QI?

When we say QI, we are referring to the science of QI developed over the past few decades by Dr. W. Edwards Deming and Dr. Joseph Juran, and promoted by Dr. Donald Berwick of the Institute for Healthcare Improvement (IHI). QI is based on an understanding of the system in which we function, the complexity of dealing with people, the variation of outcomes created by the system and the use of knowledge to influence those outcomes. QI initiatives are applied by local staff and leaders who are proficient at problem solving and managing group dynamics, and involve the people being served in the design of how care is delivered.

A QI initiative has the following features:

- Local interdisciplinary teams empowered and trained to set goals for improvement
- Teams identifying causes of problems, barriers to quality or flaws in system design that lead to poor quality
- Teams trying out different ideas for improving how care is delivered in multiple brief, small experiments of change
- Teams conducting frequent, targeted measurement of quality in a way that gives them instant feedback on whether the changes they are testing are heading in the right direction

What is healthcare QI?

“A broad range of activities of varying degrees of complexity and methodological and statistical rigour through which healthcare providers develop, implement and assess small-scale interventions, identify those that work well and implement them more broadly in order to improve clinical practice.”

QI science provides tools and processes to assess and accelerate QI efforts through testing, implementation and spread. But QI is more than tools; it is a culture of continuous Quality Improvement. QI uses structured improvement methods and models, including the Model for Improvement, Six Sigma and Lean. It makes use of incremental change and a testing model called Plan-Do-Study-Act (PDSA). And it acknowledges that successful QI requires leadership from senior management and clinicians, an appropriate and supportive culture, and people trained in group processes and change management. All of this needs to be aligned with the organization’s strategic objectives, and with the quality management systems in place. LTC is an important part of the Ontario healthcare system, providing care to 76,000 residents.

A LTC QI project, like any other project, has a beginning, a middle and an end. The LTC QI team has a defined aim, gathers relevant data and develops and tests changes as they work towards implementing successful improvements. It is assumed that any LTC QI project fits into an organizational framework that supports and promotes Continuous QI (CQI).

1 The Ethics of Improving Health Care Quality & Safety: A Hastings Center/AHRQ Project, Mary Ann Baily, PhD, Associate for Ethics & Health Policy, The Hastings Center, Garrison, New York, October, 2004
A successful QI project team uses structured improvement models and methods similar to those discussed in this guide. In some cases, the QI project team is a group of people already working together as a resident care team. However, it is most common for a team to come together as a unique group, with each member selected to provide input into a particular aspect of the process being addressed. However it is constituted, the QI project team works together to achieve the project aim.

1.3 WHAT CAN YOU EXPECT FROM THIS GUIDE?

This guide is intended as a jumping off point in the QI journey, and provides foundational knowledge necessary to start improvement projects. HQO has developed modules focused on various change concepts and strategies, including access and efficiency. We will develop additional modules to address other crucial elements that support the success and spread of Ontario QI initiatives.

This document is divided into three main sections:

- **LTC QI Project Cases** — An introduction to structured improvement methods and examples of projects
- **QI Model for Improvement** — More details about the structured improvement model, including discussions and examples related to each component
- **QI Methods and Tools** — Examples of methods and templates of tools presented in the earlier sections of the guide, with a particular focus on their use in LTC

LINK! LTC QI teams can optimize quality by improving access and efficiency. HQO has developed two modules, focused on access and efficiency, to accompany this guide. They are available on the website at www.hqontario.ca.
2.1 INTRODUCTION

Ideas for resident care improvements come from countless sources. Leaders may identify a gap related to organizational objectives, or teams may identify opportunities based on provider and resident experiences. In some cases, quality monitoring issues, public reporting on quality indicators or new best practice guidelines serve as an impetus for QI projects.

This guide presents a methodology — the Model for Improvement — and tools that a team can use to make improvements. QI practitioners have found this methodology and these tools useful over the past 20 years. Keep in mind that the Model for Improvement is a framework for making improvements. Within each project, a number of tools and techniques may be useful on their own or in combination. No two projects will be identical in their tests of change or the tools and techniques they use, but there are common situations in which specific tools might be useful. The right tool at the right time can help construct a great outcome.

There are two LTC QI case studies in this section. These are not actual cases, but amalgams of real case studies. In the sidebar next to each story, we provide a list that refers the reader to the key QI tools and techniques relevant to the LTC team's QI journey.
The new director of an LTC home pointed out that the organization’s falls rate was much higher than that of other similar organizations. After explanations from staff that the home’s resident population was much sicker, managers and clinicians finally agreed that the rate was too high.

The director held a facility-wide “Falls Fair” to educate staff about the common causes of resident falls and prevention. Unfortunately, the falls rates for the next three months remained high.

Looking at the data, the organization saw that the unit with the highest number of falls cared for relatively mobile residents with mild to moderate dementia who were getting stroke rehab. The director created a QI team made up of an associate director of care (ADOC), a registered practical nurse (RPN), an aide and a rehabilitation therapist.

At the first team meeting, everyone had a lot to say about the causes for the large number of falls. They questioned why things happened as they did and had many suggestions for change. Working with the team leader, the team’s facilitator described IHI’s Model for Improvement and rapid cycle improvements.

At their second meeting, the team worked to clarify their project aim, and then set an improvement target of 40%. To find out more about their falls, the team looked at a year’s worth of incident data and the reason for each fall.

Much has been written about falls reduction, with evidence from successful programs, and this offered many good improvement ideas. The team decided to implement a falls risk assessment process to prevent falls.

The first task was to find examples of falls risk assessment tools. One tool developed by another organization with a similar resident population seemed promising, and the team planned a small test. Jim, the RPN, tried the tool with two cognitively aware residents to see how long it took and whether the tool seemed workable. Jim presented his results: with a few tweaks, he thought the tool could be used for the majority of the residents in the unit.

Jane, the ADOC, worked with a unit nurse to see how she felt about using the tool. After several more PDSA cycles, the assessment process began to work. Within two weeks, test results were available on almost all residents in the unit.

The team then started working on how the risk assessment could trigger a falls prevention protocol that included multiple strategies (strength/balance training, medication review, simple changes such as bed height adjustments, etc).

Over the following months, the team continued to test changes, measure results and build changes into the procedures and orientation for new staff. After nine months, the falls rate had reached and sustained the team’s target. The home celebrated its successes and continued the work to maintain and increase the improvement. Administration supported the spread of the new changes and procedures, and encouraged other units to test them.
Staff at the Langley Home suspected that they had a problem, and a new look at MDS data confirmed it: their 79% incontinence rate was much higher than provincial comparison figures. Not only was this a major quality of life issue for residents, but it was also a resource issue. Fortunately, much work has been done on improving continence care, and staff realized that a 50% reduction in the incontinence rate should be possible.

The administrator struck a team. The team included RPNs, Personal Support Workers (PSWs), Life Enrichment staff and Environmental staff. They enlisted a physician's help when needed. The first step was for all team members to meet to discuss the reasons for the high incontinence rate. Participants shared many reasons and challenges, as well as suggestions for improvement.

The team decided to use the Model for Improvement with its emphasis on PDSA cycles. They agreed on a project aim to guide their work and help focus their efforts: “improve care for residents at the Langley Home by reducing the incontinence rate by 50% through an enhanced toileting program that is safe for residents and staff.”

The team settled on four change concepts: 1) use an individualized toileting plan of care for every appropriate resident; 2) standardize and improve care documentation; 3) increase awareness and expertise related to continence care; and 4) make it easier for residents to use the toilet.

In addition to the crucial incontinence rate, some obvious outcome measures to track included the cost of incontinence products, the number of residents with a toileting plan and the change rate. Balancing measures were falls and pressure ulcer rates, staff injury time and workload measurement indicators.

Dozens of good ideas were available about how to improve continence care in ways that were directly tied to the team’s project aim and change concepts. Various groups had developed best practice guidelines and assessment tools the team could use. Finally, there were examples from dozens of other homes and hospitals that had improved their continence care.

As a first step towards understanding the current process related to assessment, documentation and care planning, the team mapped out all the steps and activities as they were currently done. This demonstrated how fragmented, incomplete and haphazard the whole process was. It was a wonder that any assessments were ever completed! It also showed why the assessments did not usually lead to resident improvements. Although everyone used the same assessment tool, subsequent steps were different for every unit and sometimes for every nurse in the unit.

The team also realized that it had no idea how many residents had had an assessment and how current it was. They devised a simple Check Sheet to collect this information. Two aides took on the responsibility of reviewing every chart and completing the Check Sheet. The team reviewed the data and discovered that, although many residents had had an assessment, most were not current.

The team worked to redesign the assessment process and developed standard methods for responding to information learned during assessments. Now nurses summarize information and discuss cases with physicians, and then develop detailed care plans for residents.

The team, and later other teams in other parts of the Langley Home, continued to use PDSA to improve continence care and spread improvements throughout the organization. They worked diligently for 12 months and succeeded in decreasing their incontinence rate by more than 50%. Their other outcome measures showed substantial improvement, as did their balancing measures.
2.2 OBSERVATIONS ON THE CASE STUDIES

Although the two case studies are different and did not follow exactly the same path, there are commonalities between them and with most other successful LTC QI projects:

- LTC QI projects are team-driven
- QI work starts with a strong aim statement that the team may revisit after they understand their problem better
- Teams decide what measures they should collect
- Teams identify strategic areas for improvements or key change ideas
- Teams use a series of PDSA cycles to develop and test small changes on a small scale in different contexts; after building confidence that the changes do lead to improvement, teams implement the changes
- Management and teams work to spread improvements to other parts of the organization, if appropriate

The PDSA cycles, supported within the Model for Improvement, provide structure for changes and the learning process. The next chapter discusses the Model for Improvement and how to use it.

2.3 SUMMARY

The LTC QI journey has multiple phases, with each step building on the previous one. For example, you must analyze your current processes before you can implement improvements. Furthermore, all settings can use QI tools to map and understand their processes, and using the right tools will allow the team to work smarter rather than harder.

The PDSA cycle is a way to keep LTC QI initiatives small and manageable and, at the same time, to generate momentum by creating early successes. Building on each cycle of PDSA, for each category of change being tested, helps teams achieve short- and long-term goals.

The rest of this guide offers an introduction to start you on your way. We recommend that you talk to colleagues, share ideas and share stories so that everyone can learn from each other’s experiences.
3.1 INTRODUCTION

The Model for Improvement has two basic components: the first addresses three fundamental questions, and the second is the rapid cycle improvement process comprising a series of PDSA cycles to develop, test and implement changes for improvement (see Figure 1).

The Model for Improvement is a simple but powerful framework for structuring any QI project. QI teams that use this model have the highest chance of success. This chapter focuses on the components of the model.

![Model for Improvement Diagram](image-url)
3.2 ASSEMBLING THE TEAM: WHO SHOULD BE ON THE LTC QI TEAM?

To be successful, an LTC QI initiative needs the support of the whole team — from the PSWs, Registered Nurses (RN), RPNs, ADOCs, administrators, allied professionals, environmental staff, dietary/food services staff, life enrichment/programming staff, and other. Though the team needs to be inclusive, inviting a maximum of 10 people to join keeps it manageable. Identify a leader who is respected and has credibility among peers. Be open to including constructive skeptics who have legitimate concerns but are open to change. Sometimes, teams choose to include a member from outside their service group because of an inter-dependency with other parts of the system. For example, a team may invite a representative from a nearby hospital to contribute to strategies related to hospital transfers.

Consider the following checklist when forming a team:

- Have we included a representative from each discipline that touches the work?
- Have we considered including non-regulated staff who also support the work?
- Have we identified a team leader?
- Should we have a physician champion on the team?
- Should we include a constructive skeptic on our team?
- Do we have someone with QI skills to facilitate our progress?
- Should we consider an external stakeholder?

TIP! The people who do the work need to be the ones to change the work.

3.3 DEFINING THE AIM: WHAT ARE WE TRYING TO ACCOMPLISH?

Every LTC QI initiative needs a clearly defined aim. The aim should answer the question, “What are we trying to accomplish?” It should also have the following characteristics:

- **Clear** — To create a clear plan, you need a clear aim.
- **Time-specific** — Set a goal date for when you want to accomplish your aims.
- **Stretchable** — To support your aim, establish a stretch goal. Aiming for small, incremental change (e.g., moving from below average to average, or changing by 10%) does not represent a real breakthrough in quality, and may not justify the investment in people’s time to participate. To help you set a stretch goal, look at what leaders in the field are doing. If there are no clear examples of leading practices, aim to decrease suboptimal care, adverse events or undesirable wait times by half as a first step.
- **Providing real value** — Ensure that your aim has real value to your residents.

**EXAMPLE**

**Poor aim statements:**

“Through the implementation of an electronic medical record (EMR), our residents at risk for pressure ulcers will get better care.”

or

“We will create a truly interdisciplinary team to provide specialized resident-centred care for those with pressure ulcers.”

**Good aim statements:**

“We will improve the prevention of pressure ulcers for residents in our home. By May of next year, we will aim to decrease the prevalence and incidence of pressure ulcers by 75%; prevalence from the current 20% to below 5%, and incidence from the current 10% to below 2.5%.”
3.4 IDENTIFYING THE MEASURES: HOW WILL WE KNOW IF A CHANGE IS AN IMPROVEMENT?

Measures tell you whether the changes you make are actually leading to tangible improvement. They give you concrete evidence to support your case for change, and they also increase buy-in for the initiative.

3.4.1 Types of measures

QI initiatives should use three types of measures to help create targets and achieve their aims:

- **Outcome measures** are the “voice of the resident” and capture system performance. In other words, what are the results? Examples include pressure ulcer rates and falls rates.
- **Process measures** are the “voice of the workings of the system.” In other words, are the steps in the processes that support the system performing as planned? Examples include risk assessment rates for falls and pressure ulcers, rates of engagement for residents in your care and high-risk resident intervention rates.
- **Balancing measures** look at a system from different perspectives. In other words, are changes designed to improve one part of the system causing new problems in other parts of the system? Examples include staff satisfaction, financial implications and restraint rates (when implementing a falls prevention program).

3.5 DEFINING THE CHANGES: WHAT CHANGES CAN WE MAKE THAT WILL RESULT IN IMPROVEMENT?

**Change ideas** are specific changes that focus on improving specific steps of a process. They are practical ideas that can be readily tested.

**Change concepts**, on the other hand, are the broader principles that provide general direction for planning improvements.

*For example,* “engage the resident in his or her care” is a change concept. Discussing falls prevention strategies with the resident and his or her family, and asking them to “teach back” is a change idea.
3.5.1 Change ideas

LTC QI teams may have ideas about what changes need to be made. It is important to tap into the wisdom of the group when considering possible areas for improvement.

First, identify all the different ideas for addressing a problem or improving care by:

- Asking the team for ideas
- Seeking best practices from other LTC homes or other organizations
- Creating process maps or fishbone diagrams to identify where problems are occurring and potential solutions
- Considering generic change concepts (a general approach to improving quality) and then brainstorming about how to adapt/apply these ideas in a local setting

Second, narrow down the list of ideas to the changes that are most likely to result in improvement. Using measures to understand current processes will help to identify the changes the team should explore further.

3.5.2 Change concepts

Many change concepts offer improvement opportunities to LTC homes:

- Lean focuses on change concepts to reduce waste
- Six Sigma focuses on change concepts to improve the reliability of a process
- Advanced access change concepts focus on reducing delays for appointments
- Efficiency change concepts promote flow within health services

Here are some examples of change concepts, along with change ideas that a LTC QI team can use to apply the change concepts:

<table>
<thead>
<tr>
<th>CHANGE CONCEPT</th>
<th>CHANGE IDEAS RELATED TO THE CHANGE CONCEPT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remove constraints</td>
<td>Arrange for the personal support worker to explain educational handouts, freeing up the registered staff to assess residents</td>
</tr>
<tr>
<td>Use visual cues</td>
<td>Place a visible sticker above the bed of residents who are at high risk for pressure ulcers to trigger staff to carry out interventions</td>
</tr>
<tr>
<td>Have contingency plans</td>
<td>Develop a vacation scheduling plan to ensure that supply is able to meet anticipated demand</td>
</tr>
</tbody>
</table>

See Appendix A for examples of Change Concepts
3.6 IMPLEMENTING RAPID CYCLE IMPROVEMENTS: WHAT ARE PLAN-DO-STUDY-ACT (PDSA) CYCLES?

3.6.1 Testing and implementing change ideas

This section describes tools that help LTC QI teams test and refine change ideas, and then implement them more broadly.

Once you have identified possible LTC QI change ideas, test each of them thoroughly using a quick succession of small tests, and trying different variations and combinations of ideas. Use the PDSA cycles and ramps (described in detail in Section 3.6.3 and 3.6.4) to implement and assess the change, and to keep the team and project on track. After analyzing the results, spread successful changes to other parts of the organization.

PDSA cycles offer the most robust approach for improvements, because what seems to be a cutting-edge practice in one place may not work well somewhere else. It may have to be adapted to your environment, since every organization has a different mix of skills, people, equipment and policies. Also, the residents that an organization serves will vary in age, culture, language, education and socioeconomic status.

Trying to change a system all at once can generate resistance. We often fear change, are skeptical about the benefits and are attached to old ways of doing things. Small tests of change can be a low-risk way to try new ideas that people might be hesitant about at first. They can demonstrate the benefits of a new initiative and encourage buy-in.

Furthermore, any change may have unintended consequences. Small tests of change can help uncover undesirable effects early so the LTC QI team can modify or abandon a change idea.

3.6.2 Laying the groundwork before conducting PDSA cycles

Before you start to conduct PDSA cycles:
1. Organize your change ideas into groups, each of which represents a similar notion or approach to change, or change concept
2. Decide which change ideas are high-priority and should be tested first (use the system analysis tools described in Section 4.1 to help identify priorities)
3. Identify different ways each change idea could be implemented

Now you are ready to start your PDSA cycles.
3.6.3 Step-by-step instructions for conducting PDSA cycles

You can use PDSA cycles to develop change ideas, test small-scale changes and implement changes across your LTC area and organization.

Follow these steps to conduct a PDSA cycle:

<table>
<thead>
<tr>
<th>Step 1</th>
<th>PLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>State the purpose of the PDSA — are you developing a change idea, testing a change or implementing a change?</td>
</tr>
<tr>
<td></td>
<td>What is your change idea?</td>
</tr>
<tr>
<td></td>
<td>What indicator(s) of success will you measure?</td>
</tr>
<tr>
<td></td>
<td>How will data on these indicators be collected?</td>
</tr>
<tr>
<td></td>
<td>Who or what are the subjects of the test?</td>
</tr>
<tr>
<td></td>
<td>How many subjects will be included in the test and over what time period?</td>
</tr>
<tr>
<td></td>
<td>What do you hypothesize will happen?</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 2</th>
<th>DO</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Conduct the test.</td>
</tr>
<tr>
<td></td>
<td>Document any problems and unintended consequences.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 3</th>
<th>STUDY</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Analyze the data and study the results</td>
</tr>
<tr>
<td></td>
<td>Compare the data to your predictions.</td>
</tr>
<tr>
<td></td>
<td>Summarize and reflect on what was learned.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 4</th>
<th>ACT</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Refine the change idea, based on lessons learned from the test.</td>
</tr>
<tr>
<td></td>
<td>Prepare a plan for the next test.</td>
</tr>
</tbody>
</table>

TOOLS

You can find a full-sized copy of the PDSA Worksheet template, pictured here, in the sample tools section of this guide. You can also download the latest template from www.hqontario.ca.

TIP!

Remember to document all PDSA cycles. This is important to keep track of changes that led to an improvement and will enable you to annotate run charts — a graphical way of tracking your data, described in the next chapter.
3.6.4 Using PDSA ramps

Each change idea requires a series of PDSA cycles to test it — possibly first with one resident, expanding to two or three residents, and then expanding to a larger group of residents. This process of using a series of PDSA cycles to test an idea is called a PDSA ramp. The LTC QI team can implement PDSA ramps one after the other or simultaneously.

In Figure 2, an LTC home is trying to reduce the occurrence of pressure ulcers. The LTC QI team is considering three change concepts represented by each of three PDSA ramps. The first tests a change idea to improve self-management; the second tests a change idea for high-risk rounds; and a third tests a change idea for a reminder system linked to the resident turning schedule.

Along the “resident self-management” ramp, the team might try a series of PDSA cycles to test giving residents and their families information about how to reduce the risk of pressure ulcers. This would involve giving one resident and his or her family a copy of a pressure ulcer prevention brochure, seeing whether the resident uses that information to improve self-management and asking for resident feedback on the brochure. The next cycle might involve two or three residents and their families, again assessing the impact on their self-management and asking for feedback, and so on, until residents and their families agree the brochure is user-friendly, and it is shown to support self-management for a defined group of residents.

FIGURE 2 | Example of LTC Pressure Ulcer Prevention PDSA Ramps
3.6.5 The project charter: Pulling it all together

A QI project charter documents your aim and describes your QI initiative. Specifically, it sets out the purpose, scope, measures and targets for success. It identifies the key members of the QI team and specifies the time and resources to be invested, as well as the potential payoff. A clear project charter provides focus and promotes success.

QI is consistent with key elements of project management, as well as good business practices. It addresses problems that are important to the organization, promotes cost avoidance and ensures high-quality service that increases resident and provider satisfaction. Long term care settings can promote the organizational spread of their improvements by documenting the information outlined in the project charter so the benefits of the improvement project are clearly articulated.

Dr. Deming’s philosophy is that “by adopting appropriate principles of management, organizations can increase quality and simultaneously reduce costs (by reducing waste, rework, staff attrition and litigation while increasing customer loyalty).”

INTRODUCTION: WHAT ARE OUR QUALITY PROBLEMS?

The first step in planning a LTC QI initiative is to analyze your processes and understand the problems.

A process is a series of connected steps or actions to achieve an outcome. It has a start point and an end point. A process has a purpose and function of its own, but it cannot work entirely by itself. Rather, it interacts with the system as a whole. To improve a process, you must refine and optimize the steps in that process, making it more efficient.

There are a variety of QI methods and tools that are relevant at different times during a project or to meet specific needs. For example, there are tools that help you understand and analyze your process, as well as tools that show the impact of your changes using graphical and statistical methods.

4.1 TOOLS THAT HELP YOU UNDERSTAND AND ANALYZE YOUR LTC PROCESS

QI science offers a variety of tools to help identify the source of quality problems and focus improvement efforts. Each tool has its own purpose, and it is important to select the right tool for each analysis. The following table lists the QI tools described in this chapter and when to use them.

<table>
<thead>
<tr>
<th>TOOL</th>

</tr>
</tbody>
</table>

The tools described in this section are available as templates at www.hqontario.ca, where you can also find examples and further explanations.
4.1.1 Fishbone/Ishikawa/Cause & Effect Diagrams

The Fishbone Diagram, also known as an Ishikawa Diagram or Cause & Effect Diagram, is a simple tool that can be used to brainstorm and map out possible causes of a LTC quality problem. A Fishbone Diagram (see Figure 3) is an important first step, because many LTC QI teams jump into trying to fix one cause without assessing other possible causes.

**Step-by-step instructions**

1. Put the name of the quality problem (the effect) in the box at the far right of the diagram.
2. To the left of this box, draw a central line (the spine), and from this central line draw diagonal lines (fish bones) representing different groupings of causes of the problem. For example, some teams use the five Ps (person/resident, providers/staff, policies, processes/procedures, and place/equipment); some use the six Ms (machine, method, materials, measurement, man and Mother Nature); and some use the four Ss (surroundings, suppliers, systems and skills). Pick groupings that make the most sense for your organization and problem.
3. Ask your LTC QI team members to identify different causes and list them along the appropriate diagonal line or grouping.
4. Team members may take any cause and draw a line and more branches off the line to describe other factors that contribute to the cause.
After deciding on the major groupings, allow plenty of opportunity for group creativity in identifying different causes. Encourage teams to consider all arms of the diagram, and not to focus too much attention on only one or two categories of causes. This is brainstorming, and it is best not to discuss the ideas during this part of the activity.

Once the Fishbone Diagram is complete, the LTC QI team can start reviewing it to understand and analyze the cause(s) of the problem (or effect). The LTC QI team can also use the Fishbone Diagram to document ideas they may not address initially, but want to consider in the future.

**Process-style Fishbone Diagram**

Depending on your setting, you may find it helpful to use the Fishbone Diagram to analyze a particular process or service. In that case, you can use the process-style variation (see Figure 4):

1. Identify some key processes used to deliver a service where there is a quality concern.
2. Plot these processes in a horizontal sequence.
3. Draw diagonal lines from each process.
4. Ask LTC QI team members to identify problems that arise at each step or process and plot them along each diagonal line.

**Example of a Process-style Fishbone Diagram**

In this process-style Fishbone Diagram, we have mapped the process from collecting resident laundry to washing and returning it.

![Figure 4: Process-style Fishbone Diagram](image-url)
4.1.2 Five Whys

The Five Whys is a simple brainstorming tool that can help LTC QI teams get to the root causes of a problem. For a problem you have identified (either using the Fishbone Diagram or Process Mapping), ask “why” questions to drill down to the root causes. This tool allows teams to move beyond obvious answers and reflect on less obvious explanations.

**Step-by-step instructions**

1. State the problem you have identified as a strategic problem to work on.
2. Start asking why questions related to the problem. Like an inquisitive toddler, keep asking why in response to each suggested cause.
3. Ask as many whys as you need in order to get insight at a level that can be addressed (asking five times is typical).

The Five Whys is a strategy that is often used to further explore an issue identified using another tool, such as a Fishbone Diagram or Process Mapping. Guard against using the Five Whys questions on their own to avoid a narrow focus or bias.

**The Five Whys at Work**

An LTC home was concerned that residents at risk for pressure ulcers were not being turned on a reliable basis, as specified in the care plan. The LTC QI team used a process-style Fishbone Diagram to get some context. They discovered from a Check Sheet that the main cause of the delay was the fact that 30% of personal support workers (PSWs) were not aware of the turning details of the care plan. They then used the Five Whys to get at the actual cause.

Why are PSWs not aware of the turning schedule? Many are contracted and are unaware of how to see this information. Why are they unaware of how to see this information? They don’t ask, or we don’t ensure that they understand. Why? Our practices don’t strongly support the orientation of contracted staff. Why don’t our orientations support them better? … Maybe we should provide a better orientation!

Based on this analysis, the registered staff revised their education and orientation for contracted PSWs. As a result, no PSWs are unaware of the turning details of the care plan, and the pressure ulcer prevention program is achieving success.

**TIP!**

It is recommended that you create a Fishbone Diagram first, and then use Whys to dig into the causes that the LTC QI team believes are most important. Drill into the specific causes where you can make a change.
4.1.3 Process Mapping

A Process Map, also known as a flowchart, outlines all the different steps in a process — for example, all the steps that an LTC home takes to deliver a particular kind of service. Process Mapping helps LTC QI teams identify problems that can be fixed. It is a fundamental tool that should be used with all LTC QI initiatives because it gives the team clear insight into its processes. If the team cannot agree on where the problems occur, data should be collected to support each argument.

LTC QI teams should start with a high-level Process Map (with five to 12 steps). They may then choose to go into greater detail on any particular set of processes where problems are believed to be the greatest, and generate a more detailed Process Map.

Step-by-step instructions

1. Assemble a group to work on the Process Map. Include representatives of every category of staff who contributes significantly to the service. Include users and/or residents.
2. Use a neutral facilitator.
3. Agree on the first and last steps or activities — the start and end points that will be mapped.
4. Focus on mapping the steps or activities that account for 80% of what’s happening. (Don’t waste time on the exceptions.)
5. Map the actual — not the ideal — process.
6. Write each process identified on a post-it note and display it on a white board. (You may want to specify who does the process and where.)

If key team members are not able to meet together to build the Process Map, try this alternative:

1. Post a white board with processes partially mapped in a location providers pass through frequently (e.g., a lunch or staff room).
2. Invite providers to use post-it notes to add missing parts of the process. If someone disagrees with how part of a process is mapped, he or she can post an alternative set of processes below.
3. Leave the board up for a set period of time (e.g., one day or one week).

Different types of Process Mapping

There are several different types of Process Mapping:

- **Detailed** — the most common kind of Process Map
- **High-level** — the fastest, simplest and least detailed Process Map
- **High-low** (also called **Top-down**) — adds depth to a high-level Process Map, but without detailed mapping
- **Swim lane** — shows what different functions/people do in a detailed Process Map

A Process Mapping worksheet is available at [www.hqontario.ca](http://www.hqontario.ca).
Each type of Process Mapping frames the process a little differently. To decide which map to use, you need to understand how you need to visualize your process based on your particular needs during a project. Sometimes a high-level Process Map is all you need. You may opt to create detailed or swim lane Process Maps on subsets of your process only when you need them. Resist the desire to map all parts of your process in detail!

1. Detailed Process Map

The detailed Process Map usually maps processes in a sequential manner from start to finish (see Figure 5).

* This process map is indicative of a standard falls process; individual LTC homes may find their processes differ slightly. As ambulance response time may differ, the order of some processes while waiting for EMS arrival may be different.
When you display a Process Map, remember to include a Process Map Key (see Figure 6).

</tbody>
</table>

**FIGURE 6** | Example of a Process Map Key

### 2. High-level Process Map

A high-level Process Map is the most basic of all (see Figure 7). It lists the main steps in a process — usually five to 12 of them. It is a great start, and it is often followed by a high-low Process Map.

**FIGURE 7** | Example of a High-level process map for resident re-integration from hospital to LTC home
3. High-low Process Map

To create a High-low Process Map (see Figure 8); it lists the main steps in a process — usually five to 12 of them. It is a great start, and it is often followed by a high-low Process Map.

![Figure 8](image)

**FIGURE 8 | Example of a High-low Process Map**

The High-low Process Map can be useful if the LTC team is struggling with the appropriate level of detail. If your team has a lot of detail-oriented people on it, you can park these details, while still maintaining a view of the big picture.

4. Swim lane Process Map

In a Swim lane Process Map, each “lane” is labeled with a care team member or location that is critical for the process to succeed. Do not forget to include the resident. Each step of the process is placed in the appropriate Swim lane according to who is handling it. A Swim lane Process Map allows the LTC QI team to see how many hand-offs occur during the process from start to finish. Unnecessary hand-offs signal inefficiencies and an increased opportunity for mistakes to occur.

**Figure 9** shows the process of a resident receiving a new medication. A minimum of three hand-offs of the medication order occur during the process: from the physician to the nurse, from the nurse to the pharmacist, then to the resident. If there is a question, then the hand-offs continue back through the nurse and physician.

![Figure 9](image)

**TIP!** The Swim lane Process Map is useful for identifying hand-offs where a problem might occur, and for keeping track of who is responsible for which process.
Analyzing your Process Map

Once you have completed your Process Map, ask the following questions:

- Where are the bottlenecks? How could we address these?
- Are there inconsistencies in how things are done? What can be standardized?
- Can things be done:
  - In a different order?
  - In parallel?
  - By a different person with better or same quality, at lower or same cost?
- Can steps be located closer to each other to reduce travel?
- Does each step add value? If not, can it be eliminated?

Process Mapping is fundamental to improving quality, because it allows the team to clearly discuss and understand each step in the process.
4.1.4 Check Sheets

A Check Sheet is a simple data collection tool that can help a LTC QI team identify the most important cause of a quality problem. It can also be used to gather information on the problem or different aspects of the problem. This tool is useful when the team has identified a number of causes or a number of problems or defects, and wants to know which one is the most important.

Step-by-step instructions

1. Generate a list of the most common defects or causes. List as many as you wish — a typical list comprises six to 10 defects or causes. Include an “other” category.
2. Create a Check Sheet (see the template in the sample tools section of the guide).
3. Decide how to collect the data — i.e., going forward in time or back in time, using chart audits or other documentation.
4. Pick a timeframe for collecting data. Ideally, the timeframe should be long enough to observe at least 50 defects or causes. If you are collecting data going forward, try to keep the data collection timeframe short (e.g., one to two weeks).
5. Identify who will collect the data (e.g., the chart reviewer or service provider). Have them mark the appropriate place on the Check Sheet (see Figure 10) each time a defect or cause occurs. Provide specific instructions on how defects or causes are to be defined.
6. Plot the data on a Pareto Chart.

FIGURE 10 | Example of a Check Sheet

4.1.5 Pareto Charts

The Pareto Chart (see Figure 11) is a tool that helps teams see which causes or problems occur most frequently. The chart plots out the activities or areas that contribute most to poor quality. The Pareto Chart is based on the theory that a small number of causes will have the largest contribution to poor quality. When a few activities contribute to most of the problem, it is called the Pareto Effect. A classic Pareto Effect is observed when 20% of the causes contribute to 80% of the overall problem.

Step-by-step instructions

1. Place the data captured in the Check Sheet into a table, in descending order. From this table, calculate the percentage frequency and cumulative frequency.
2. Plot this information as a bar chart, where each vertical bar represents a different cause or problem and the left vertical axis represents the number of causes and problems/defects.
3. Identify the bar where the cumulative frequency is high relative to the number of categories.
4. Look for a Pareto Effect, where the first few categories account for most of the problems.
FIGURE 11 | Example of a Pareto Chart

PARETO CHART: REASONS WHY BLOOD WORK WAS NOT COMPLETED

An Excel Pareto Chart template (shown in Figure 11) is available at www.hqontario.ca. Click on “Tools for QI Teams,” then “Analysing Your System,” then “Pareto Charts.”
4.2 MEASUREMENT

4.2.1 Creating a LTC QI Measurement Plan

Identify how frequently you want to collect and show data (e.g., daily, weekly or monthly). It must be frequently enough that your LTC QI team will be able to assess the impact of changes as they are testing them. Collect information related to each of your project’s outcome, process and balancing measures using a Measurement Plan template to assist you. The template will help you clarify how you will collect data, and how often. It will also prompt you to outline particular sampling strategies or system analysis strategies you may decide to use.

Wherever possible, collect data that gives you a detailed picture of each individual’s experience. For example, how many minutes it took for staff to respond to each call bell signal. Do this even if your analysis might eventually be about a percentage of residents receiving a target level of response.

Key measurement guidelines

- Choose measures that support the team’s aim statement
- Use existing data collection systems, whenever possible
- Integrate measurement into the daily LTC home routine
- Plot measures each month
- Use a set of five to seven measures to track progress throughout your QI project

Sometimes, QI teams need simple ways to collect data in order to be able to collect it frequently enough to assess the impact of changes. Two simple ways to collect data are mini-surveys and sampling.
4.2.2 Mini-surveys

Mini-surveys can help a LTC QI team determine a baseline for quality, analyze the possible causes of poor quality and identify potential solutions before starting the LTC QI initiative. Mini-surveys are a particularly good way to test change ideas before implementing them. They can also be used during a LTC QI initiative to monitor progress.

**TIP!** Mini-surveys can show whether a particular small test of change is resulting in improvement, and provide data for the “Study” part of Plan-Do-Study-Act cycles.

**Step-by-step instructions**

1. Design your survey. Select one to five questions and keep them simple.
2. Pre-test the survey questions on five to 10 people.
3. Create a sampling plan. How many people will you survey? Whom will you survey? When?
4. Identify a method to distribute the surveys and collect the results. If you are surveying residents about a service they receive, collect the data immediately after the service is provided, if possible. A simple one-page or half-page paper survey works well.
5. Provide an anonymous method for people to submit completed surveys (e.g., a shoebox with a slot) to protect resident confidentiality.

**TIP!** Count how many surveys were put out and how many remain at the end of the day. This allows you to calculate an overall response rate.

4.2.3 Sampling

Block sampling and systematic sampling are the two main methods of QI sampling.

<table>
<thead>
<tr>
<th>METHOD</th>
<th>DESCRIPTION</th>
<th>EXAMPLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Block Sampling</td>
<td>Make x observations consecutively. Do this at regular intervals.</td>
<td>Every 15th day, give a mini-survey to the first 10 family members who arrive.</td>
</tr>
<tr>
<td>Systematic Sampling</td>
<td>Make observations on every nth resident.</td>
<td>I want 10 chart reviews per week. There are 200 residents in the home. So, I’ll review every 20th chart, starting with a different resident each week.</td>
</tr>
</tbody>
</table>
To track your measures effectively, it’s important to develop a data collection plan. This will involve discussing where and how to obtain the data required for your measures, identifying data sources and deciding on a sampling plan.

**DATA SOURCES:** In an ideal situation, the LTC QI team will be able to use existing automated data sources — such as a LTC Home’s information technology (IT) system or electronic resident charts — to obtain the data they need for their measures. If these data sources are not available, the team may consider adapting the IT system to collect the new data, creating a new automated system or collecting data manually. If you are collecting data manually, keep the information required brief and focused.

**SAMPLING PLAN:** As part of the data collection plan, the team will decide how often to collect data — for example, daily, weekly, bi-weekly or monthly. Measures should be collected frequently enough to guide the project. For LTC QI initiatives, smaller and more frequent data collection or sampling is helpful. The team will also decide on the timeframe for reporting results from the data collection.

When working towards improvement, analyze your data using techniques that display the variation in the process. To do this, employ one of the charts outlined in the next section.

### 4.3 DEMONSTRATING YOUR IMPACT

Analyzing data over a period of time makes it easier to assess the impact of LTC QI changes. A graphical display of results is very useful to show changes in measures across the life cycle of a project. Both run charts and control charts can achieve this.

Run charts are useful regardless of how much data you have collected. They are simple to produce and interpret, and they are guided by simple rules. Control charts provide a more powerful way of analyzing your results, though they require more data for input and more sophistication to produce and interpret.

**TIP!**

- Plot data over time
- Track a few key measures over time — this is the single most powerful strategy a team can use
- Try not to aggregate data (e.g., show consecutive individual residents’ number of falls, rather than the average number of falls over a one-month period)
- Display the data as soon as possible after the event
4.3.1 Run charts

Run charts should be set up at the start of a QI project and updated with new data as the project unfolds. A run chart is a graph that illustrates changes in quality over time. Measurements are taken at frequent points in time and connected with a line. This provides a graphical display of variation across time, and can help a team see if their changes have led to improvement.

An annotated run chart (see Figure 12) has comments with arrows pointing to times when different ideas for improvement were tested. This helps explain any sudden changes in quality that may have occurred.

**FIGURE 12** | Example of an Annotated Run Chart

**Step-by-step instructions**

1. As you gather your data, create a graph where the measure of quality is on the vertical axis and time is on the horizontal axis. Connect each data point with a line.
2. Show your target for improvement by drawing a horizontal line across the graph, labeled “target.”
3. Show the median point of your data by drawing a horizontal line across the graph at the level where half the data points are above, and half are below that line.
4. Annotate the run chart with comments to tell the story of the different improvements the team has tried.
### Percentage of Residents with Diabetes in Riverwind LTC Home with Good Blood Sugar Control (HbA1c <0.07)

<table>
<thead>
<tr>

<td>53%</td>
<td>55%</td>
<td>55%</td>
<td>56%</td>
<td>59%</td>
<td>62%</td>
<td>63%</td>
</tr>
</tbody>
</table>

LTC QI teams can recognize significant changes — hopefully, improvements — by carrying out two simple tests on a run chart (see Figure 13):

1. Are there six or more consecutive points above the median?
2. Are there six consecutive points moving upward or downward?
If we see evidence of either of these rules in our chart, it indicates that a significant change has occurred within the process. Now, the LTC QI team’s task is to maintain progress and continue to improve.

Once a run chart has more than 11 points, consider turning it into a control chart.

### 4.3.2 Control charts

Control charts are like run charts, but they have much more statistical power to detect changes and improvements. This section of the guide provides an introductory look at control charts, including their construction and interpretation.

#### When to use control charts, and with what data

Control charts are used for QI, and also for performance monitoring (e.g., dashboards or scorecards). Data may be presented in various forms:

- Percentages
- Rates
- Counts
- Individual values
Many kinds of control charts are needed to work with different types of data — but all control charts look similar and are interpreted in much the same way.3

**Understanding variation: common and special cause**

Control charts help LTC QI teams understand the nature of the variation of their processes. They may answer questions such as:

- Do we have a stable or in-control process with common cause variation?
- Do we have an out-of-control process with special cause variation?
- What does the variation tell us about the level and range of performance of the process?

Variation is to be expected. Processes rarely produce the same measurements every time. It takes different times to get to work; golf scores vary; blood pressures fluctuate; staff routines are never identical; and dining room waiting times vary from one resident to the next.

The combination of small variations of a process adds up to common cause variation. Control charts can demonstrate whether a process is in statistical control (showing only common cause variation) or showing special cause variation. In LTC QI projects, we test and implement changes to try to influence the process to show improvements, and this would be “special cause.”

Common cause variation means that no one thing in particular is causing the result. When we travel to work, for example, all sorts of things contribute to how long it takes: traffic volumes may vary; the number of red lights may vary; and the number of people making left-hand turns may vary. Sometimes, however, variation in a process is due to a special cause. For example, we are driving to work and have to take a long detour because of a water main break. Special cause variation can often be attributed to something unusual, rare or difficult to identify. If it isn’t unusual or rare, it is probably common!

---

3 It is beyond the scope of this guide to describe all the possible types of data and related control charts. You’ll find references to useful discussions of control charts at the end of the section. Software is available that makes charting relatively easy.
Control chart fundamentals

A control chart is a run chart with a line drawn at the average (or mean), and pairs of control limits. The control limits are calculated to show one, two and three standard deviation (SD) lines for the plotted data. Most if not all control charts show three SD limits, commonly called the upper control limit (UCL) and lower control limit (LCL). A point beyond one of the three SD limits is evidence that a special cause probably occurred. The LTC QI team’s job is to figure out what this might be. Sometimes, as the example of a long detour on the way to work showed, the reason is very obvious. But often it is not.

What about the one and two SD limits? Statisticians have determined that there are other ways data can show special cause — cases when different patterns of measurements involve the other limits. There are many rules, some very similar to rules used to interpret run charts. For example, if we were to see two out of three consecutive measurements beyond a two SD line, this would be statistically unusual and is evidence that a special cause may have occurred. If we see eight points in a row above or below the average, that again indicates a special cause.

EXAMPLE, PART 2

The person helping the LTC QI team build a control chart decided it would be best to look at the average of medication errors per 1,000 bed days. The team’s expectation was that the error rate should have been reduced after all the improvements they had made. The analyst constructed a control chart called an XbarR chart. She constructed the chart using the original data and used those limits to test for a special cause in the following weeks (see Figure 16).

Despite considerable variation, and a relatively poor overall average, the data from the original review did not show any special cause. This data was in statistical control with a high degree of variation.

Although it took time to show it, the process improved and several instances of special cause were observed. Although no measure ever exceeded a three SD control limit, the third week after starting to make changes, eight consecutive data points were below the original average. This suggested that the changes were starting to make noticeable improvements.

The team continued to work on improving the various processes in their LTC home, and realized they needed to draw a new control chart because their new process was consistently better than their old one.
Control chart interpretation

We look at control charts to see if there is any evidence of special cause in the charted data. Special cause can be observed in several ways, using a number of rules.

If we do not see evidence of special cause, it means our process is in statistical control. We then want to look at the average value and where the limits are. Looking at the average tells us whether the process is good or not on average. A process could be in control, and still be a poor process — “some residents always get their meals late at this home!” It could also be that there are very wide limits around the average. Imagine that residents typically wait an average of 10 minutes to be served their dinner, but on some days the average wait time is 15, 20 or even 25 minutes. The overall average may be acceptable, but the variation around it may be unacceptable.
When you have special cause variation, you want to understand why (see Figure 17). In the case of a LTC QI project, the “why” may be because you introduced a change and wanted to see a special cause signal that indicates you’ve made an improvement. In other situations, when you are monitoring a process, special cause may indicate something that you do not want to happen. For example, injuries due to falls may increase, risk assessments may be done too infrequently or resident satisfaction may be too low. In these instances, you want to investigate and find out what happened.

If you are trying to improve your processes, but are not seeing a special cause signal, revisit your tests of change using PDSA and use tools that help you analyze your system.

Control charts are ideally suited to monitoring improvement project outcomes and process measures and helping to determine whether a change is actually an improvement. Easy-to-use software is available.
**RULE 1**
Any point above the UCL or below the LCL

**RULE 2**
Any two out of three consecutive points fall beyond two standard deviations above or below the mean

**RULE 3**
Any four out of five consecutive points fall beyond one standard deviation above or below the mean

**RULE 4**
Eight consecutive points fall on one side of the mean
4.4 CONCLUSION

Current reporting on LTC quality shows that Ontario has some leading practices and programs, but there is also ample room for improvement. Organizations are increasingly interested in leveraging their success to strengthen existing QI activities and develop new QI projects. This guide is meant to serve as a resource for LTC QI practitioners and teams to allow them to continue to develop QI skills sets and expand their QI toolkit.

The guide provided case studies to illustrate the progression of QI projects within LTC and the many resources available to LTC QI teams. It covered the fundamentals of the Model for Improvement and rapid cycle improvements, which often help drive the new culture of Continuous QI. It also shared methods and practical tips to help teams more readily analyze their current processes and identify opportunities for improvement.

It is hoped that this guide provided both guidance and practical tools to help QI practitioners across the LTC sector succeed in their aims.

Readers can find updated versions of the guide and all of HQO’s QI tools, templates and recommended resources at www.hqontario.ca.
Many popular change concept groupings, including the two described here, share common themes. These examples are a small sample of the many change concepts available to LTC QI teams.

### EFFICIENCY IMPROVES THE FLOW OF A PROCESS, WHILE REDUCING WASTE.

<tr>
<td>Optimize Inventory</td>
<td>Reduce and control inventory at all levels of the organization.</td>
</tr>
<tr>
<td>Change the Work Environment</td>
<td>The work environment itself offers a great opportunity to seek efficiencies — for example, by moving related steps closer together.</td>
</tr>
<tr>
<td>Evaluate the Producer/Customer Interface</td>
<td>Focus on the connections between residents and providers, and the elements that are important to the resident in that interface.</td>
</tr>
<tr>
<td>Manage Time</td>
<td>Reduce delays, wait times and cycle times for all services.</td>
</tr>
<tr>
<td>Focus on Variation</td>
<td>Reduce variation to improve quality processes and outcomes.</td>
</tr>
<tr>
<td>Conduct Error Proofing</td>
<td>Redesign the system to make it less likely for people in the system to make errors.</td>
</tr>
<tr>
<td>Focus on the Product or Service</td>
<td>Focus on the quality of the actual service (and product), as well as on the process improvement.</td>
</tr>
</tbody>
</table>

### MISTAKE PROOFING IS THE PRACTICE OF DESIGNING A PROCESS OR SYSTEM TO PREVENT ERRORS OR MINIMIZE THEIR EFFECT.

<table>
<thead>
<tr>
<th>MISTAKE PROOFING CHANGE CONCEPT</th>
<th>COMMENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Forcing Function</td>
<td>Design the system so that it is impossible to make an error.</td>
</tr>
<tr>
<td>Constraining Function to an error.</td>
<td>Design the system so that it constrains some component from being able to lead</td>
</tr>
<tr>
<td>Reminders and Alerts</td>
<td>Generate a reminder when a particular step needs to be done.</td>
</tr>
<tr>
<td>Avoiding Look-alikes</td>
<td>Avoid instances where two items, names, processes or residents look the same. Rename or recode one or more items.</td>
</tr>
<tr>
<td>Visual cues</td>
<td>Label or visually code items so that it is easy to spot when they are in the wrong place.</td>
</tr>

**Objective for this PDSA Cycle**

Is this cycle used to:

- [ ] develop or [ ] test or [ ] implement a change?

What question(s) do we want to answer on this PDSA cycle?

**PLAN:**

**DO:**

*Carry out the change or test, collect data and begin analysis.*

**STUDY:**

*Complete analysis of data.*

*Compare data to predictions and summarize what was learned.*

**ACT:**

*Are we ready to make a change? Plan for the next cycle.*
“If you can’t draw a picture of your process, you can’t improve anything.”

Dr. W. Edwards Deming
## MEASUREMENT PLAN TEMPLATE

### QI Project:

### Timeframe for Project:

</tbody>
</table>

**How do your outcome and process measures link to your organization’s corporate dashboard?**

**Will you measure causes of poor quality?**  □ Yes  □ No  
*If so, for which measures of quality?*

**Will you collect baseline data?**  □ Yes  □ No  
*If yes, what is the timeframe for the baseline?*

**Will you use sampling for any manual data collection methods?**  □ Yes  □ No  
*If yes, for each data collection method, indicate sampling method (block or systematic) and protocol.*
Use this data to produce Pareto Charts to discover common reasons for problems and focus on improvement opportunities.

Organization/Unit Name: ____________________________________________

Topic Question: ____________________________________________________

Examples of topic questions:
Why aren’t residents being turned as per care plan?
Why aren’t residents receiving screenings as per protocol?

Location Specifics: ____________________________________________

Data Recorders: ____________________________________________

Start Date: ____________________________

End Date: ____________________________
